

Case A: Large smooth-margin benign nodule misclassified as malignant

Clinical input

History: 57-year-old White male; current smoker

Location: left upper lobe

Size: 18.0 x 15.0 mm

Morphology: solid; smooth margins; soft-tissue attenuation

Gemini F3 output

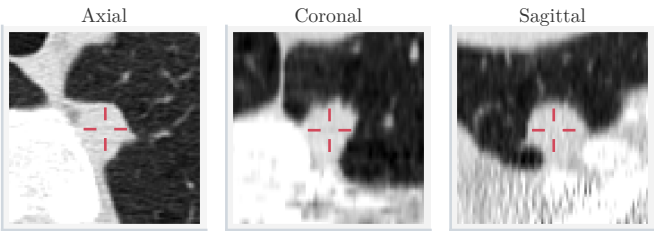

Predicted malignant

Confidence 0.85; label hidden at inference

Rationale

The large size of 18 mm in a current smoker is highly suspicious for malignancy despite the reported smooth margins.

Case B: Small spiculated malignant nodule undercalled as benign

Clinical input

History: 74-year-old White female; former/never smoker

Location: left lower lobe

Size: 4.0 x 4.0 mm

Morphology: solid; spiculated/irregular margins; mixed attenuation

Gemini F3 output

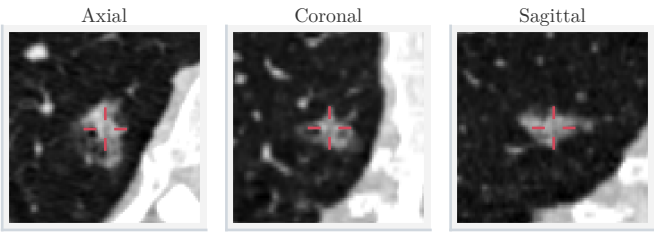

Predicted benign

Confidence 0.05; label hidden at inference

Rationale

The very small size of 4 mm and the patient's non-smoking history are highly suggestive of a benign nodule despite the reported irregular margins.

Case C: Mixed-attenuation benign nodule overcalled as malignant

Clinical input

History: 69-year-old White female; current smoker

Location: right upper lobe

Size: 16.0 x 13.0 mm

Morphology: solid; spiculated/irregular margins; mixed attenuation

Gemini F3 output

Predicted malignant

Confidence 0.92; label hidden at inference

Rationale

The nodule's large size of 16 mm combined with spiculated margins in a 69-year-old smoker strongly indicates malignancy.
